## Major Depressive Disorder (MDD) in Children under Age 6

### Level 0
Comprehensive assessment. Refer to *Principles of Practice* on page 6.

### Level 1
Psychotherapeutic intervention (e.g., dyadic therapy) for 6 to 9 months; assessment of parent/guardian depression and referral for treatment if present.

### Level 2
If poor response to psychosocial treatment after 6 to 9 months, re-assess diagnosis, primary care giver response to treatment, and/or consider switching to a different or more intensive psychosocial treatment. Consider child psychiatric consultation or second opinion.

Under 3 years, refer to *Principles of Practice* on page 6.

### Level 3
If depression is severe, or there is continued poor response to psychosocial treatment alone, consider combination treatment with fluoxetine and concurrent psychosocial treatment.

- **Fluoxetine — 4 to 5 years old**
  - Maximum dose: 5 mg/day
  - Discontinuation trial after 6 months of any effective medication treatment with gradual downward taper.
  - **Monitor for behavioral disinhibition and suicidality.**
    Behavioral disinhibition is defined as impulsive, sensation seeking behaviors and lack of self-regulation.

### Not Recommended:
- The use of medication without psychosocial treatment.
- Use of tricyclic antidepressants (TCAs) or paroxetine.

*Note: In preschool children, MDD is very rare (point prevalence is thought to be 0.5%).*
Major Depressive Disorder (MDD) in Children and Adolescents Ages 6 to 17 Years Old

Level 0

Assessment

- Screening using multi-informant, validated rating scales that include depression and screening for comorbidity (other psychiatric and medical conditions):
  - Center for Epidemiological Studies Depression Scale for Children Patient Health Questionnaire (CES-DC)
  - Patient Health Questionnaire-9 (PHQ-9)
  - Pediatric Symptom Checklist (PSC)

  Note: The above scales are available at [http://medicaidmentalhealth.org/](http://medicaidmentalhealth.org/).

- Specific screen for harm to self or others and access to firearms, knives/sharps, and other lethal means such as alcohol, prescription and non-prescription medications.

- Evaluate sleep hygiene, diet, and exercise.

- Address environmental stressors such as abuse, bullying, conflict, functioning at school, peer relationships, and caregiver depression.

- Specific screen for harm to self/others.

- Establish a safety plan:
  - Removal of firearms, knives/sharps, and other lethal means such as alcohol, prescription and non-prescription medications.
  - Develop an emergency action plan:
    - Provide adolescents with mutually agreeable and available emergency numbers and contacts.
    - Engage a concerned third party familiar with the adolescent.

- Positive screen: DSM-5 based interview evaluation.

- Consider medical reason for depression (e.g., hypothyroidism, B12/folate deficiency, anemia, malnutrition (with or without eating disorder), chronic disorder (diabetes, asthma, inflammatory bowel disease, juvenile rheumatoid disease, infectious mononucleosis, etc.).

- Rule out iatrogenic etiology of depression (i.e., medication side effects/interactions).

- Evaluate past psychiatric and medical history, previous treatment, family conflict and current depression of family and caregivers, bullying, abuse, peer conflict, school issues and substance abuse.

- Consider and rule out presence of bipolar depression. Pointers: Prior (hypo)mania, family history of bipolar disorder, atypical depression with reverse neurovegetative signs, seasonal affective component, brief and recurrent episodes, and melancholic depression in prepubertal child.
**Level 0 (continued)**

  *Note: The Child Depression Inventory is not available in the public domain.*

Always monitor for:

- Emergence or exacerbation of suicidality and balance the risk–benefit profile of antidepressants during the acute treatment phase.
- Behavioral activation (e.g., difficulty falling asleep, increased motor activity, increased talkativeness)
- Adverse events
- Treatment adherence
- Treatment or inherently emergent comorbidity
- Potential development of (hypo)mania

**Level 1**

Initial treatment plan

- Active support: 6 week trial (if mild symptoms).
  - Components of active support must include psychosocial interventions and psychoeducation and may include: Self-help materials, active listening/relationship building, school involvement, mood monitoring, pleasant activities, cognitive restructuring, family conflict reduction, sleep hygiene, and exercise.
### Level 2
Reassess diagnosis first (e.g., bipolar disorder), rule out psychostimulant or substance abuse related psychosis. Targeted treatments if symptoms are moderate to severe, impairment continues, and/or no response to active support. Start with cognitive behavioral therapy (CBT), Interpersonal therapy (IPT), depression-specific behavioral family therapy.

- **2a.** Fluoxetine or combination of CBT or IPT psychotherapy with fluoxetine (COMB).
- **2b.** May consider use of escitalopram for age 12 and above.

**Qualifiers:**
- Mild: Psychosocial interventions only.
- Moderate/Severe: COMB.
- Psychosis: SSRIs (fluoxetine, escitalopram) plus antipsychotic.
- Comorbidity: COMB, treat comorbidity.
- Suicidality: intensify surveillance and follow-up; COMB if on antidepressant only or remove antidepressant if otherwise ineffective; if chronic, consider lithium augmentation.

### Level 3
Inadequate response
- If no clinical response to the medication utilized in Level 2, switch to another medication listed above.

### Level 4
Poor or non-response
- Refer to mental health specialist.
- Re-assess diagnosis (bipolar disorder, substance use disorder, anxiety disorders, PTSD), rule out medical condition (e.g., hypothyroidism), or medication side effects.
- Increase psychosocial intervention and medication dose if tolerated.
- Augment with alternate psychosocial intervention (either CBT or IPT).
- Consider change in level of care (treatment setting and interventions based on severity of illness).
- For milder form and/or seasonal affective symptoms with light sensitivity, consider bright light therapy.
Level 5
If poor or non-response to Level 4 interventions
◆ Switch previously used SSRIs to sertraline, citalopram, bupropion or venlafaxine, especially in those who do not have access to psychotherapy or have not responded to non-pharmacological interventions.
◆ Consider augmentation of SSRI with bupropion, thyroxine, lithium, buspirone, mirtazapine, aripiprazole, quetiapine, or risperidone (adult data only).
◆ If psychotic/severe: ECT (for adolescents).

Notes:
◆ Factors favoring maintenance treatment (at any Level):
  ◆ Partial response
  ◆ Prior relapse
  ◆ Suicidality
  ◆ Comorbidity risk for relapse
  ◆ Environmental risk for relapse
  ◆ Family history of relapsing/recurrent major depression
  ◆ Lack of return to full premorbid functioning
◆ Maintenance treatment: 9 to 12 months.
◆ After maintenance treatment: If stable, at level of premorbid functioning, and no anticipated increase in stressors, consider discontinuation trial over 3 to 4 months.

Note on pharmacogenomic testing: The current evidence does not support pharmacogenomic testing in routine psychiatric clinical practice.
